Ecosystem Destruction and Burning

1	Aim	Avoid environmental damage for obtaining or managing organic farmland.
2	Background	Cutting and burning woodland is common practice in many countries, to obtain new farmland, or to destroy fallow vegetation. Besides, burning is used for weed control on field margins, to promote grass re-sprouting on natural grassland, and for destruction of crop residues.
		These traditions may be time-efficient and help to release in a short-term considerable amounts of plant nutrients, but they involve serious environmental damage, like species extinction, global warming, and loss of soils. Destruction of primary forests is the most outstanding environmental problem all over the tropics. Besides timber exploitation, slash and burn aims basically at obtaining farm and pasture land. Consumers, who pay higher prices for organic food, tend to have a high level of environmental consciousness, and expect organic food to be produced without such damaging practices.
3	Normative framework	EU-Regulation: Reg. (EC) 834/07, Preamble (1): "Organic production is an overall system of farm management and food production that combines best environmental practices, a high level of biodiversity, the preservation of natural resources," Art. 3 Organic production shall pursue the following general objectives: (a) establish a sustainable management system for agriculture that: (i) respects nature's systems and cycles and sustains and enhances the health of soil, water, plants and animals and the balance between them; (ii) contributes to a high level of biological diversity; Art 5 Specific principles applicable to farming In addition to the overall principles set out in Article 4, organic farming shall be based on the following specific principles: (a) the maintenance and enhancement of soil life and natural soil fertility, soil stability and soil biodiversity preventing and combating soil compaction and soil erosion, and the nourishing of plants primarily through the soil ecosystem. NOP: § 205.2 (Definitions) Organic production: A production system that is managed in accordance with the Act and regulations in this part to respond to site-specific conditions by practices that foster cycling of resources, promote ecological balance, and conserve biodiversity. § 205.200: Practices implemented in accordance with this subpart must maintain or improve the natural resources of the operation § 205.203: (e) The producer must not use: (3) Burning as a means of disposal for crop residues produced on the operation: Except, that, prunings from perennial crops may be burned to suppress the spread of disease. Also refer to the NOP Handbook 5020 which further specifies the requirements regarding biodiversity and natural resource conservation.
4	Terms, clarifications, abbreviations	Shifting cultivation: Traditional farming system, especially in the tropics, where forest areas are slashed, burned, and cultivated during some years, and then left for regeneration of secondary forest vegetation, before the land is subject to re-cultivation.

5.3 Cutting and burning of forests of lower ecological value and burning of forests of lower ecological value a. Secondary or fallow vegetation of lower ecological value can be cut to obtain farmiand in areas, where sufficient other forest or similar resources exist, provided that local authorities permit this practice. b. In case of burning of such vegetation, the respective plot has to undergo at least one year of (additional) transition. Exceptions can be made, where smallholders have definitely no technical alternatives to burning, like chainsaws and/or tractor ploughing. 5.4 Burning of field margins, weeds and crop residues must not be burned for other reasons than avoiding the spread of plant diseases and pests. Time efficiency in weed control is not sufficient as an argument for burning. 5.5 Specific case ginger production China A very common system for ginger production in China is to cut down forests, plant ginger for 1 or 2 years, and then re-forest the area again. Such a system can be certified organic only under the following conditions: a. The forest that is planted on the area, after harvesting the ginger, has at least a similar ecological value as the forest that was cut down. E.g. a Pinus or Abies or Eucalyptus plantation does not have the same ecological value as a mixed stand of broad leaf and conifer trees. b. The ginger production does not contribute to soil erosion. Even if the land is reforested immediately after the ginger crop, in the short period of ginger cropping, a very significant amount of soil can be lost on steep slopes. To prevent this, e.g. contour lines with shrubs and/or individual trees should be maintained at adequate distances, instead of destroying the entire original vegetation. c. Wood, including branches and leaves and other forest vegetation, that are not used for other purposes (timber, fuelwood), must be left to decompose, and must not be burned. Confirmations from forest authorities in the different countries can be considered, but are ultimately not crit		,
